# 1 Advice

## Pre-submit:

Are time limits close? If so, generate max cases.  
Is the memory usage fine? Could anything overflow? Make sure to submit the right file.

Wrong answer: Print your solution! Print debug output, as well. Are you clearing all datastructures between test cases? Can your algorithm handle the whole range of input?

Read the full problem statement again. Do you handle all corner cases correctly? Have you understood the problem correctly? Any uninitialized variables? Any overflows? Confusing N and M, i and j, etc.? Are you sure your algorithm works? What special cases have you not thought of?

Are you sure the STL functions you use work as you think? Add some assertions, maybe resubmit. Create some testcases to run your algorithm on. Go through the algorithm for a simple case.

Go through this list again. Explain your algorithm to a team mate. Ask the team mate to look at your code. Go for a small walk, e.g. to the toilet. Is your output format correct? Rewrite your solution from the start or let a team mate do it.

Runtime error: Have you tested all corner cases locally? Any uninitialized variables? Are you reading or writing outside the range of any vector? Any assertions that might fail? Any possible division by 0? (mod 0 for example). Any possible infinite recursion? Invalidated pointers or iterators? Are you using too much memory? Debug with resubmits.

Time limit exceeded: Do you have any possible infinite loops? What is the complexity of your algorithm? Are you copying a lot of unnecessary data? (References) How big is the input and output? (consider scanf) Avoid vector, map. (use arrays/unordered\_map) What do your team

mates think about your algorithm?

Memory limit exceeded: What is the max amount of memory your algorithm should need? Are you clearing all datastructures between test cases?

Primes - 10001st prime is 1299721, 100001st prime is 15485867 Large primes - 999999937,  $1e9+7$ , 987646789, 987101789; 78498 primes less than  $10^6$  The number of divisors of n is at most around 100, for  $n < 5e4$ , 500 for  $n \leq 1e7$ , 2000 for  $n < 1e10$ , 200,000 for  $n < 1e19$   $7! = 5040$ ,  $8! = 40320$ ,  $9! = 362880$ ,  $10! = 362880$ ,  $11! = 4.0e7$ ,  $12! = 4.8e8$ ,  $15! = 1.3e12$ ,  $20! = 2e18$

The number of divisors of n is at most around 100 for  $n < 5e4$ , 500 for  $n < 1e7$ , 2000 for  $n < 1e10$ , 200 000 for  $n < 1e19$ .

Articulation points and bridges articulation point :- there exist child :  $\text{dfslow}[\text{child}] \geq \text{dfsnum}[\text{curr}]$  bridge :- tree ed:  $\text{dfslow}[\text{ch}] > \text{dfsnum}[\text{par}]$ ;

A connected multigraph has an Euler path but not an Euler circuit if and only if it has exactly two vertices of odd degree

Binomial coefficients - base case  $\text{ncn}$  and  $\text{nc0} = 1$ ; recursion is  $\text{nCk} = (\text{n-1})\text{C}(\text{k-1}) + (\text{n-1})\text{Ck}$

Catalan numbers - used in valid paranthesis expressions - formula is  $\text{Cn} = \sum_{i=0}^{n-1} (\text{CiCn-i-1})$ ; Another formula is  $\text{Cn} = \frac{2n\text{Cn}}{(n+1)}$ . There are  $\text{Cn}$  binary trees of n nodes and  $\text{Cn-1}$  rooted trees of n nodes

Derangements -  $D(n) = (n-1)(D(n-1) + D(n-2))$

Burnsides Lemma - number of equivalence classes =  $(\sum I(\text{pi}))/n$  :  $I(\text{pi})$  are number of fixed points. Usual formula:  $[\sum_{i=0}^{n-1} k^{\text{gcd}(i,n)}]/n$

Stirling numbers - first kind - permutations of n elements with k disjoint cycles.  $s(n+1,k) = ns(n,k) + s(n,k-1)$ .  $s(0,0) = 1$ ,  $s(n,0) = 0$  if  $n > 0$ .  $\sum_{k=0}^n s(n,k) = n!$

Stirling numbers - Second kind - partition n objects into k non empty subsets.  $S(n+1,k) = kS(n,k) + S(n,k-1)$ .  $S(0,0) = 1$ ,  $S(n,0) = 0$  if  $n > 0$ .  $S(n,k) = (\sum_{j=0}^k [(-1)^{(k-j)} \binom{k}{j} j^n]) / k!$

Hermite identity -  $\sum_{k=0}^{n-1} \text{floor}[(x+k)/n] = \text{floor}[nx]$

Kirchoff matrix tree theorem - number of spanning trees in a graph is determinant of Laplacian Matrix with one row and column removed, where  $L$  = degree matrix - adjacency matrix

Expected value tricks:

1. Linearity of Expectation:  $E(X+Y) = E(X) + E(Y)$
2. Contribution to the sum - If we want to find the sum over many ways/possibilities, we should consider every element (maybe a number, or a pair or an edge) and count how many times it will be added to the answer.
3. For independent events -  $E(XY) = E(X)E(Y)$
4. Ordered pairs (Super interpretation of square) - The square of the size of a set is equal to the number of ordered pairs of elements in the set. So we iterate over pairs and for each we compute the contribution to the answer. Similarly, the k-th power is equal to the number of sequences (tuples) of length k.
5. Powers technique - If you want to maintain the sum of k-th powers, it might help to also maintain the sum of smaller powers. For example, if the sum of 0-th, 1-th and 2-nd powers is  $S_0$ ,  $S_1$  and  $S_2$ , and we increase every element by x, the new sums are  $S_0$ ,  $S_1 + S_0x$  and  $S_2 + 2S_1x + x^2S_0$ .

## 2 Aho Corasick

```
struct AhoCorasick{
    enum {alpha=26,first='a'};
    struct Node{
        int back, next[alpha], start = -1, end = -1,
            nmatches = 0;
        Node(int v){memset(next,v,sizeof(next));};

}

```

## 6 Euler Path

procedure FindEulerPath(V)

1. iterate through all the edges outgoing from vertex V;  
remove **this** edge from the graph,  
and call FindEulerPath from the second end of **this** edge;
2. add vertex V to the answer.

## 7 Extended Euclidean GCD

```

int egcd(int a,int b, int* x, int* y){
    if(a==0){
        *x=0;*y=1;
        return b;}
    int x1,y1;
    int gcd=egcd(b%a,a,&x1,&y1);
    *x=y1-(b/a)*x1;
    *y=x1;
    return gcd;}

```

## 8 Fast Fourier Transform

```

using cd = complex<double>;
const double PI = acos(-1);

```

```

void fft(vector<cd> & a, bool invert) { //invert =
    1 for inverse FFT
    int n = a.size();

    return g;}
// dfs find all bridges and g contain bridge tree
// rest is diameter calculation

```

## 42 Z Algorithm

```

// Z Algorithm
// Z[i] is the length of the longest substring
// starting from S[i]
// which is also a prefix of S
// O(n)
void z_func(v32 &s,v32 &z){
    int L=0,R=0;
    int sz=s.size();
    z.assign(sz,0);
    forsn(i,1,sz){
        if(i>R){
            L=R=i;
            while(R<sz && s[R-L]==s[R]) R++;
            z[i]=R-L; R--;
        }else{
            int k=i-L;
            if(z[k]<R-i+1) z[i]=z[k];
            else{
                L=i;
                while(R<sz && s[R-L]==s[R]) R++;
                z[i]=R-L; R--; }}}}

```

## 43 Z Ideas

Gray codes Applications:

1. Gray code of n bits forms a Hamiltonian cycle on a hypercube, where each bit corresponds to one dimension.
2. Gray code can be used to solve the Towers of Hanoi problem. Let n denote number of disks. Start with Gray code of length n which consists of all zeroes (G(0)) and move between consecutive Gray codes (from G(i) to G(i+1)). Let i-th bit of current Gray code represent n-th disk (the least significant bit corresponds to the smallest disk and the most significant bit to the biggest disk). Since exactly one bit changes on each step, we can treat changing i-th bit as moving i-th disk. Notice that there is exactly one move option for each disk (except the smallest one) on each step (except start and finish positions).

There are always two move options for the smallest disk but there is a strategy which will always lead to answer:

if n is odd then sequence of the smallest disk moves looks like ftrftr ... where f is the initial rod, t is the terminal rod and r is the remaining rod),  
and if n is even: frtfrt ....  
int gray (int n) {return n ^ (n >> 1);}
int rev\_g (int g) {
 int n = 0;
 for (; g; g >>= 1) n ^= g;
 return n;}

Enumerating all submasks of a bitmask:

```

for (int s=m; ; s=(s-1)&m) {
    ... you can use s ...
    if (s==0) break;}

```

Sparse Table:

```

int st[MAXN][K];
for (int i = 0; i < N; i++) st[i][0] = array[i];
for (int j = 1; j <= K; j++)
    for (int i = 0; i + (1 << j) <= N; i++)
        st[i][j] = min(st[i][j-1], st[i + (1 << (j
            - 1))][j - 1]);

```

To get minimum of a range:

```

int j = log[R - L + 1];

```

```
int minimum = min(st[L][j], st[R - (1 << j) + 1][j]);
```

Divide and Conquer DP:

Some dynamic programming problems have a recurrence of this form:

$dp(i, j) = \min_k \{dp(i, k) + C(k, j)\}$  where  $C(k, j)$  is some cost function.

Say  $1 \leq i \leq n$  and  $1 \leq j \leq m$ , and evaluating  $C$  takes  $O(1)$  time.

Straightforward evaluation of the above recurrence is  $O(nm^2)$ .

There are  $nm$  states, and  $m$  transitions for each state.

Let  $opt(i, j)$  be the value of  $k$  that minimizes the above expression.

If  $opt(i, j) \leq opt(i, j+1)$  for all  $i, j$ , then we can apply

divide-and-conquer DP. This known as the monotonicity condition.

The optimal "splitting point" for a fixed  $i$  increases as  $j$  increases.

```
int n;
long long C(int i, int j);
vector<long long> dp_before(n), dp_cur(n);
// compute dp_cur[l], ... dp_cur[r] (inclusive)
void compute(int l, int r, int optl, int optr)
{
    if (l > r)
        return;
    int mid = (l + r) >> 1;
    pair<long long, int> best = {INF, -1};

    for (int k = optl; k <= min(mid, optr); k++) {
        best = min(best, {dp_before[k] + C(k, mid), k});
    }
    dp_cur[mid] = best.first;
    int opt = best.second;
    compute(l, mid - 1, optl, opt);
    compute(mid + 1, r, opt, optr);
}
```

Knuth Optimization:

$dp[i][j] = \min_{i < k < j} \{dp[i][k] + dp[k][j]\} + C[i][j]$   
 monotonicity :  $C[b][c] \leq C[a][d]$   
 quadrangle inequality:  $C[a][c] + C[b][d] \leq C[a][d] + C[b][c]$

Lyndon factorization: We can get the minimum cyclic shift.

Factorize the string as  $s = w_1 w_2 w_3 \dots w_n$

```
string min_cyclic_string(string s) {
    s += s;
    int n = s.size();
    int i = 0, ans = 0;
    while (i < n / 2) {
        ans = i;
        int j = i + 1, k = i;
        while (j < n && s[k] <= s[j]) {
            if (s[k] < s[j])
                k = i;
            else
                k++;
            j++;
        }
        while (i <= k)
            i += j - k;
        return s.substr(ans, n / 2);
    }
}
```

Rank of a matrix:

```
const double EPS = 1E-9;

int compute_rank(vector<vector<double>> A) {
    int n = A.size();
    int m = A[0].size();
    int rank = 0;
    vector<bool> row_selected(n, false);
    for (int i = 0; i < m; ++i) {
        int j;
        for (j = 0; j < n; ++j) {
            if (!row_selected[j] && abs(A[j][i]) > EPS)
                break;
        }
        if (j != n) {
            ++rank;
            for (int k = i + 1; k < m; ++k)
                for (int l = j + 1; l < n; ++l)
                    A[l][k] -= A[j][k] * A[l][i];
        }
    }
    return rank;
}
```

```
row_selected[j] = true;
for (int p = i + 1; p < m; ++p)
    A[j][p] /= A[j][i];
for (int k = 0; k < n; ++k) {
    if (k != j && abs(A[k][i]) > EPS) {
        for (int p = i + 1; p < m; ++p)
            A[k][p] -= A[j][p] * A[k][i] / A[j][i];
    }
}
return rank;
}
```

Determinant of a matrix:

```
const double EPS = 1E-9;
int n;
vector<vector<double>> a(n, vector<double>(n));

double det = 1;
for (int i = 0; i < n; ++i) {
    int k = i;
    for (int j = i + 1; j < n; ++j)
        if (abs(a[j][i]) > abs(a[k][i]))
            k = j;
    if (abs(a[k][i]) < EPS) {
        det = 0;
        break;
    }
    swap(a[i], a[k]);
    if (i != k)
        det = -det;
    det *= a[i][i];
    for (int j = i + 1; j < n; ++j)
        a[i][j] /= a[i][i];
    for (int j = 0; j < n; ++j)
        if (j != i && abs(a[j][i]) > EPS)
            for (int k = i + 1; k < n; ++k)
                a[j][k] -= a[i][k] * a[j][i] / a[i][i];
}
cout << det;
```

Generating all  $k$ -subsets:

```
vector<int> ans;
void gen(int n, int k, int idx, bool rev) {
    if (k > n || k < 0) return;
    if (!n) {
        for (int i = 0; i < idx; ++i) {
            ans.push_back(i);
            if (rev) reverse(ans.begin(), ans.end());
        }
    }
}
```

```

        if (ans[i]) cout << i + 1;}
    cout << "\n";
    return;}
    ans[idx] = rev;
    gen(n - 1, k - rev, idx + 1, false);
    ans[idx] = !rev;
    gen(n - 1, k - !rev, idx + 1, true);}
void all_combinations(int n, int k) {
    ans.resize(n);gen(n, k, 0, false);}

```

Simpsons formula for integration:

```

const int N = 1000 * 1000; // number of steps (
    already multiplied by 2)
double simpson_integration(double a, double b){
    double h = (b - a) / N;
    double s = f(a) + f(b); // a = x_0 and b = x_2n
    for (int i = 1; i <= N - 1; ++i) { // Refer to
        final Simpson's formula
        double x = a + h * i;
        s += f(x) * ((i & 1) ? 4 : 2);}
    s *= h / 3;
    return s;}

```

Picks theorem:

Given a certain lattice polygon with non-zero area .

We denote its area by  $S$ , the number of points with integer coordinates lying strictly inside the polygon by  $I$  and the number of points lying on polygon sides by  $B$ .

Then, the Pick formula states:  $S = I + B/2 - 1$   
In particular, if the values of  $I$  and  $B$  for a polygon are given, the area can be calculated in  $O(1)$  without even knowing the vertices.

Strongly Connected component and Condensation Graph:

```
vector < vector<int> > g, gr;
```

```

vector<bool> used;
vector<int> order, component;

void dfs1 (int v) {
    used[v] = true;
    for (size_t i=0; i<g[v].size(); ++i)
        if (!used[ g[v][i] ]) dfs1 (g[v][i]);
    order.push_back (v);}
void dfs2 (int v) {
    used[v] = true;
    component.push_back (v);
    for (size_t i=0; i<gr[v].size(); ++i)
        if (!used[ gr[v][i] ]) dfs2 (gr[v][i]);}
int main() {
    int n;
    ... reading n ...
    for (;;) {
        int a, b;
        ... reading next edge (a,b) ...
        g[a].push_back (b);
        gr[b].push_back (a);
    }
    used.assign (n, false);
    for (int i=0; i<n; ++i)
        if (!used[i]) dfs1 (i);
    used.assign (n, false);
    for (int i=0; i<n; ++i) {
        int v = order[n-1-i];
        if (!used[v]) { dfs2 (v);
            ... printing next component ...
            component.clear();
        }}}

```

FFT Matrices:

XOR FFT:  $1 \ 1 \ / \ 1 \ -1$ , AND FFT:  $0 \ 1/ \ 1 \ 1$ , OR FFT:  $1 \ 1/ \ 1 \ 0$

Harmonic lemma:

```

for (int i = 1, la; i <= n; i = la + 1) {
    la = n / (n / i);
    v.pb(mp(n/i,la-i+1));}
//n / x yields the same value for i <= x <= la.

```

Mobius inversion theory:

if  $f$  and  $g$  are multiplicative, then their dirichlet convolution, i.e  $\sum_{d|x} f(d)g(x/d)$  is also multiplicative. eg. choose  $g = 1$

Properties:

1. If  $g(n) = \sum_{d|n} f(d)$ , then  $f(n) = \sum_{d|x} g(d)u(n/d)$ .
2.  $\sum_{d|n} u(d) = [n==1]$

Standard question: Number of co-prime integers in range  $1, n$

Answer:  $f(n) = \sum_{d=1 \text{ to } n} u(d)\text{floor}(n/d)^2$

Euler totient:  $\phi(\text{totient fn}) = u * n$  (dirichlet convolution)

a Nim position  $(n_1, \dots, n_k)$  is a second player win in misere Nim if and only if some  $n_i > 1$  and  $n_1 \text{ xor } \dots \text{ xor } n_k = 0$ , or all  $n_i \leq 1$  and  $n_1 \text{ xor } \dots \text{ xor } n_k = 1$ .

Fibonacci Identities:

1.  $F_{n-1}F_{n+1} - F_n^2 = (-1)^n$
2.  $F_{n+k} = F_kF_{n+1} + F_{k-1}F_n$
3.  $F_n \mid F_m \Leftrightarrow n \mid m$
4.  $\text{GCD}(F_m, F_n) = F_{\text{gcd}(m,n)}$
5.  $F_{2k} = F_k(2F_{k+1} - F_k)$ .  $F_{2k+1} = F_k^2 + F_{k+1}^2$
6.  $n \geq \phi(m) \Rightarrow x^n = x^{(\phi(m) + n\% \phi(m)) \bmod m}$

Ternary Search

```

double ternary_search(double l, double r) {
    double eps = 1e-9;           //set the error
    limit here
    while (r - l > eps) {
        double m1 = l + (r - l) / 3;
        double m2 = r - (r - l) / 3;
        double f1 = f(m1);       //evaluates the
            function at m1
        double f2 = f(m2);       //evaluates the
            function at m2
        if (f1 < f2) l = m1;
    }
}

```

```

else r = m2;}
return f(1);}           //return the
maximum of f(x) in [l, r]

```

Counting labeled graphs:

The total number of labelled graphs is  $G_n = 2^{\binom{n}{2}}$   
 Number of connected labelled graphs is  $C_n = G_n - \frac{1}{n} \sum_{k=1}^{n-1} k \cdot \binom{n}{k} \cdot C_{n-k}$   
 Number of labelled graphs with  $k$  components:  $D[n][k] = \sum_{s=1}^n ((n-1)C(s-1)) C_s D_{n-s}[k-1]$

Steiner tree dp:

The idea is to build a dynamic programming  $DP[i][m]$ , where  $i$  is which vertex you are at and  $m$  is a bitmask of which capitals you joined. You can preprocess the APSP (Floyd-Warshall, or many Dijkstras because of the small constants) and calculate  $DP[i][m]$  like this:  $DP[i][m] = \min(DP[i][s] + DP[j][m-s] + \text{dist}[i][j])$ , with  $s$  being a submask of  $m$ . In the end the complexity is  $O(3^k \cdot n^2)$ .

To get  $O(3^k \cdot n)$  complexity, you do 2 transitions:  
 1.  $O(3^k \cdot n)$  transition using submasks and  
 2.  $O(2^k \cdot n^2)$  transition, that is,  $O(n^2)$  transition for each mask.

Sum of subsets DP:

$F(x) = \text{sum of all } A(i) \text{ such that } x \& i = i.$

```

//iterative version
for(int mask = 0; mask < (1<<N); ++mask){
    dp[mask][-1] = A[mask]; //handle base case
    separately (leaf states)
    for(int i = 0; i < N; ++i){
        if(mask & (1<<i))
            dp[mask][i] = dp[mask][i-1] + dp[mask^(1<<i)][i-1];
        else
            dp[mask][i] = dp[mask][i-1];
    }
    F[mask] = dp[mask][N-1];
}

```

```

//memory optimized, super easy to code.
for(int i = 0; i < (1<<N); ++i) F[i] = A[i];
for(int i = 0; i < N; ++i) for(int mask = 0; mask <
    (1<<N); ++mask){
    if(mask & (1<<i)) F[mask] += F[mask^(1<<i)];
}

```
